

Experiments

Powerful tool of causal research

Copyright A. C. Ekin 1998-2002

Experiments

Method of inferring causality

- The manipulation of an independent variable and measuring its effect on another under controlled conditions

Copyright A. C. Ekin 1998-2002

Experiments

Main design issues

- How to manipulate the independent variable(s)
- How to choose the dependent variable
- How to assign test units
- How to control extraneous variables

Copyright A. C. Ekin 1998-2002

Independent variable

Cause

- It is called independent because the researcher can decide on its value. It is also known as the experimental treatment

Copyright A. C. Ekin 1998-2002

Independent variable

Types and levels

- Independent variable may be
 - Categorical (which ad layout)
 - Continuous (which price level)
- Experimental treatment may include multiple forms of the independent variable, like:
 - Different prices
 - Different prices and different gifts

Copyright A. C. Ekin 1998-2002

Dependent variable

Effect

- Also known as the measurement
- We expect its value to be dependent on the treatments
- Measurements of the dependent variable allow the researcher to judge the experimental results

Copyright A. C. Ekin 1998-2002

Test units

Subjects of the experiment

- Researcher measures the responses of the test units to the experimental treatment using appropriate tools such as surveys or observation

Copyright A. C. Ekin 1998-2002

Test units

Selection and assignment

- Selection method affects the error level
- To reduce error, the researcher may
 - Randomly select and assign elements
 - Match the units on important variables
 - Take repeated measures to expose all units to all levels of treatment

Copyright A. C. Ekin 1998-2002

Control

The environment must be controlled

- Systematic error that may enter the study must be controlled so that the results can be attributed to the experimental treatment

Copyright A. C. Ekin 1998-2002

Control

Demand characteristics

- Procedures that intentionally hint to subjects something about the experimenter's hypothesis
- Experimental units may behave differently because
 - The presence of the experimenter may affect their behavior (experimenter bias) resulting in guinea pig effect
 - To reduce this, blinding may be used

Copyright A. C. Ekin 1998-2002

Experiments

- Important concepts in experiments

Independent variable (experimental treatment, cause)

Dependent variable (effect)

Extraneous effects (contaminants)

Experimental group (exposed to the treatment)

Control group (not exposed to the treatment)

Randomization (random selection of elements)

Validity (internal or external)

Copyright A. C. Ekin 1998-2002

Experiments

Concept of validity

- An experiment is valid if it:
 - Measures the effects of the independent variable (internal validity)
 - Its results can be applied to the world outside the experiment (external validity)

Copyright A. C. Ekin 1998-2002

Experiments

- Threats to internal validity
 - History, changes in the environment
 - Maturation, changes in units
 - Mortality, losing units
 - Selection bias, nonrandom selection
 - Testing, effect of measurement
 - Instrumentation, changes in the instrument

Copyright A. C. Ekin 1998-2002

Experiments

Threats to external validity

- Frame error in selecting the sample
 - No longer a representative sample. Improper definition of the operational population*
- Unnatural nature of the experimental environment
 - Will they behave the same way in the real world as they have behaved in the laboratory?*

Copyright A. C. Ekin 1998-2002

Experiments

Types of experiments

- Laboratory experiments
 - Experiments that take place in controlled environments*
- Field experiments
 - Experiments that take place in their natural environments*

Copyright A. C. Ekin 1998-2002

Experiments

Types of experiments

- Issues of validity

	<i>Validity</i>	
<i>Experiment</i>	<i>Internal</i>	<i>External</i>
<i>Laboratory</i>	<i>High</i>	<i>Low</i>
<i>Field</i>	<i>Low</i>	<i>High</i>

Copyright A. C. Ekin 1998-2002

Experimental design

Notation to describe designs

- O** A measurement of a dependent variable
 - X** The experimental treatment, independent variable
 - R** Randomization
 - E** Experimental effect
- Horizontal placement of symbols signify time sequence
- Vertical placement of symbols signify different groups

Copyright A. C. Ekin 1998-2002

Experimental design

Quasi experimental designs

- Quasi experimental designs do not use randomization. Consequently, their conclusions are not as robust as real experimental designs

Copyright A. C. Ekin 1998-2002

Experimental design

Quasi experimental designs

■ After only design

- X O₁

$$E = O_1$$

- The observed result is presumed to be the effect of the experimental treatment
- The design is flawed

Copyright A. C. Ekin 1998-2002

Experimental design

Quasi-experimental designs

■ Static group design

- EG: X O₁

- CG: O₂

$$E = (O_2 - O_1)$$

- The difference between the two measurements is presumed to be the effect of the experimental treatment
- This design too is flawed

Copyright A. C. Ekin 1998-2002

Experimental design

Quasi-experimental designs

- One group, before-after design (pretest-posttest)
 - $O_1 \quad X \quad O_2$

$$E = O_2 - O_1$$

- The difference between measurements taken before and after the introduction of the experimental treatment is presumed to be the effect of the experimental treatment
- Another flawed design

Copyright A. C. Ekin 1998-2002

Experimental design

Quasi experimental designs

- Before-after with control group
 - EG: $O_1 \quad X \quad O_2$
 - CG: $O_3 \quad \quad \quad O_4$

$$E = (O_2 - O_1) - (O_4 - O_3)$$

- The attempt to control the effects of external elements fails due to lack of randomization

Copyright A. C. Ekin 1998-2002

Experimental design

True experimental designs

- True experimental designs require randomization. Elements are randomly selected and randomly assigned to test and control groups.

Copyright A. C. Ekin 1998-2002

Experimental design

True experimental designs

- Posttest only with control group
 - EG: (R) $\quad X \quad O_1$
 - CG: (R) $\quad \quad \quad O_2$

$$E = (O_2 - O_1)$$

- Decent attempt to create a true experimental design
- Conditions before the introduction of the treatment are unknown

Copyright A. C. Ekin 1998-2002

Experimental design

True experimental designs

- Before after with control group and randomization
 - EG: (R) O_1 X O_2
 - CG: (R) O_3 O_4
 $E = (O_2 - O_1) - (O_4 - O_3)$
 - Many of the external factors are controlled

Copyright A. C. Ekin 1998-2002

Experimental design

True experimental designs

- Solomon four-group, six-study design
 - EG I (R) O_1 X O_2
 - CG I (R) O_3 O_4
 - EG II (R) X O_5
 - CG II (R) O_6

Highly complex and expensive design for most marketing research studies

Copyright A. C. Ekin 1998-2002

Test marketing

A field experiment

- Test marketing is an experimental procedure that provides an opportunity to test a new product or a new marketing plan under realistic market conditions to measure sales or profit potential

Copyright A. C. Ekin 1998-2002

Test marketing

Criteria used in selecting a suitable site

- Population size
- Demographic composition
- Lifestyle considerations
- Competitive situation
- Media
- Self-contained trading area
- Secrecy

Copyright A. C. Ekin 1998-2002

Test marketing

Controlling the experiment

- Small city
- Low chance of being detected
- Distribution is forced (guaranteed)
